# Aggregations with pandas and numpy

Name: Cuadra, Audrick Zander G.

Section: CPE22S3

Date: March 27, 2024

Submitted to: Engr. Roman Richard

#### About the data

In this notebook, we will be working with 2 data sets:

- Facebook's stock price throughout 2018 (obtained using the stock\_analysis <u>package</u>).
- daily weather data for NYC from the National Centers for Environmental Information (NCEI) API.

Note: The NCEI is part of the National Oceanic and Atmospheric Administration (NOAA) and, as you can see from the URL for the API, this resource was created when the NCEI was called the NCDC. Should the URL for this resource change in the future, you can search for the NCEI weather API to find the updated one.

## Background on the weather data

Data meanings:

- AWND: average wind speed
- PRCP: precipitation in millimeters
- SNOW: snowfall in millimeters
- SNWD: snow depth in millimeters
- TMAX: maximum daily temperature in Celsius
- TMIN: minimum daily temperature in Celsius

### Setup

```
1 import numpy as ny
2 import pandas as p
3
4 weather = p.read_csv('/content/weather_by_station.csv', index_col='date', parse_dates=True)
5 weather.head()
```

	datatype	station	value	station_name
date				
2018-01- 01	PRCP	GHCND:US1CTFR0039	0.0	STAMFORD 4.2 S, CT US
2018-01- 01	PRCP	GHCND:US1NJBG0015	0.0	NORTH ARLINGTON 0.7 WNW, NJ US
2018-01- 01	SNOW	GHCND:US1NJBG0015	0.0	NORTH ARLINGTON 0.7 WNW, NJ US

2018-01-

Next steps:

```
1 fb = p.read_csv('/content/fb_2018.csv', index_col='date', parse_dates=True).assign(
     trading_volume=lambda x: p.cut(x.volume, bins=3, labels=['low', 'med', 'high'])
3)
4 fb.head()
                open
                       high
                                     close
                                              volume trading_volume
         date
    2018-01-02 177.68 181.58 177.5500 181.42 18151903
                                                                IOW/
    2018-01-03 181.88 184.78 181.3300 184.67 16886563
                                                                low
    2018-01-04 184.90 186.21 184.0996 184.33 13880896
                                                                low
    2018-01-05 185.59 186.90 184.9300 186.85 13574535
                                                                low
    2018-01-08 187.20 188.90 186.3300 188.28 17994726
                                                                low
         _____
Next steps:
           View recommended plots
```

Before we dive into any calculations, let's make sure pandas won't put things in scientific notation. We will modify how floats are formatted for displaying. The format we will apply is .2f, which will provide the float with 2 digits after the decimal point:

```
1 p.set_option('display.float_format', lambda x: '%.2f' % x)
```

#### Summarizing DataFrames

We learned about agg() in the dataframe operations notebook when we learned about window calculations; however, we can call this on the dataframe directly to aggregate its contents into a single series:

```
1 fb.agg({
      'open': ny.mean,
2
3
      'high': ny.max,
4
      'low': ny.min,
5
      'close': ny.mean,
      'volume': ny.sum
6
7 })
    open
                    171.45
    high
                    218,62
                    123.02
    low
    close
                    171.51
    volume 6949682394.00
    dtype: float64
```

We can use this to find the total snowfall and precipitation recorded in Central Park in 2018:

```
1 weather.query(
2    'station == "GHCND:USW00094728"'
3 ).pivot(columns='datatype', values='value')[['SNOW', 'PRCP']].sum()

    datatype
    SNOW    1007.00
    PRCP    1665.30
    dtype: float64
```

This is equivalent to passing 'sum' to agg():

```
1 weather.query(
2    'station == "GHCND:USW00094728"'
3 ).pivot(columns='datatype', values='value')[['SNOW', 'PRCP']].agg('sum')

    datatype
    SNOW    1007.00
    PRCP    1665.30
    dtype: float64
```

Note that we aren't limited to providing a single aggregation per column. We can pass a list, and we will get a dataframe back instead of a series. nan values are placed where we don't have a calculation result to display:

```
1 fb.agg({
      'open': 'mean',
2
      'high': ['min', 'max'],
3
      'low': ['min', 'max'],
4
      'close': 'mean'
5
6 })
             open
                    high
                             low
                                  close
          171.45
     mean
                    NaN
                            NaN
                                  171.51
     min
             NaN 129.74 123.02
                                    NaN
     max
             NaN 218.62 214.27
                                    NaN
```

### v Using groupby()

Often we won't want to aggregate on the entire dataframe, but on groups within it. For this purpose, we can run <code>groupby()</code> before the aggregation. If we group by the <code>trading\_volume</code> column, we will get a row for each of the values it takes on:

1 fb.groupby('trading\_volume').mean()

After we run the groupby(), we can still select columns for aggregation

```
1 fb.groupby('trading_volume')['close'].agg(['min', 'max', 'mean'])
```

We can still provide a dictionary specifying the aggregations to perform, but passing a list for a column will result in a hierarchical index for the columns:

Next steps:

```
'open': 'mean',
      'high': ['min', 'max'],
3
     'low': ['min', 'max'],
4
5
     'close': 'mean'
6 })
7 fb_agg
                                           low
                                                          close
                    open
                            high
                    mean
                            min
                                   max
                                           min
                                                  max
                                                          mean
    trading_volume
                    171.36 129.74 216.20 123.02 212.60 171.43
          low
                    175.82 162.85 218.62 150.75 214.27 175.14
          med
         high
                    167.73 161.10 180.13 149.02 173.75 168.16
```

The hierarchical index in the columns looks like this:

View recommended plots

1 fb\_agg = fb.groupby('trading\_volume').agg({

Using a list comprehension, we can join the levels (in a tuple) with an \_ at each iteration:

```
1 fb_agg.columns = ['_'.join(col_agg) for col_agg in fb_agg.columns]
2 fb_agg.head()
```

	open_mean	high_min	high_max	low_min	low_max	close_mean	
trading_volume							11.
low	171.36	129.74	216.20	123.02	212.60	171.43	
med	175.82	162.85	218.62	150.75	214.27	175.14	
high	167.73	161.10	180.13	149.02	173.75	168.16	

We can group on datetimes despite them being in the index if we use a Grouper:

```
1 weather['2018-10'].query('datatype == "PRCP"').groupby(
2     p.Grouper(freq='D')
3 ).mean().head()
```

```
<ipython-input-17-927d8e720cd7>:1: FutureWarning: Indexing a DataFrame with a dateti
 weather['2018-10'].query('datatype == "PRCP"').groupby(
<ipython-input-17-927d8e720cd7>:3: FutureWarning: The default value of numeric_only
  ).mean().head()
            value
      date
2018-10-01
             0.01
2018-10-02
             2.23
2018-10-03
            19.69
2018-10-04
             0.32
2018-10-05
             0.97
```

This Grouper can be one of many group by values. Here, we find the quarterly total precipitation per station:

```
1 weather.query('datatype == "PRCP"').groupby(
     ['station_name', p.Grouper(freq='Q')]
3 ).sum().unstack().sample(5, random_state=1)
    <ipython-input-20-648f26f48c8d>:3: FutureWarning: The default value of numeric only
      ).sum().unstack().sample(5, random_state=1)
                                  value
    date
                                  2018-03-31 2018-06-30 2018-09-30 2018-12-31
                   station_name
      WANTAGH 1.1 NNE, NY US

                                                              438.80
                                                                          409.90
       SYOSSET 2.0 SSW, NY US
                                                              355.50
                                                                          459.90
                                      323.50
                                                  263.30
       STAMFORD 4.2 S, CT US
                                      338.00
                                                  272.10
                                                              424.70
                                                                          390.00
     WAYNE TWP 0.8 SSW, NJ US
                                      246.20
                                                  295.30
                                                              620.90
                                                                          422.00
```

Note that we can use filter() to exclude some groups from aggregation. Here, we only keep groups with 'NY' in the group's name attribute, which is the station ID in this case:

```
1 weather.groupby('station').filter( # station IDs with NY in them
   lambda x: 'NY' in x.name
3 ).query('datatype == "SNOW"').groupby('station_name').sum().squeeze() # aggregate and make a series (squeeze)
    <ipython-input-22-799de504673b>:3: FutureWarning: The default value of numeric_only in DataFrameGroupBy.sum i
      ).query('datatype == "SNOW"').groupby('station_name').sum().squeeze() # aggregate and make a series (squeez

```

Let's see which months have the most precipitation. First, we need to group by day and average the precipitation across the stations. Then we can group by month and sum the resulting precipitation. We use <code>nlargest()</code> to give the 5 months with the most precipitation:

Perhaps the previous result was surprising. The saying goes "April showers bring May flowers"; yet April wasn't in the top 5 (neither was May for that matter). Snow will count towards precipitation, but that doesn't explain why summer months are higher than April. Let's look for days that accounted for a large percentage of the precipitation in a given month.

In order to do so, we need to calculate the average daily precipitation across stations and then find the total per month. This will be the denominator. However, in order to divide the daily values by the total for their month, we will need a Series of equal dimensions. This means we will need to use transform():

```
1 weather.query('datatype == "PRCP"').rename(
    dict(value='prcp'), axis=1
3 ).groupby(p.Grouper(freq='D')).mean().groupby(
    p.Grouper(freg='M')
5 ).transform(ny.sum)['2018-01-28':'2018-02-03']
    <ipython-input-24-1e336928755e>:3: FutureWarning: The default value of numeric_only
      ).groupby(p.Grouper(freq='D')).mean().groupby(
                 prcp
          date
     2018-01-28
                 69.31
     2018-01-29
                69.31
     2018-01-30
                69.31
     2018-01-31 69.31
     2018-02-01 158.11
     2018-02-02 158.11
     2018-02-03 158.11
```

Notice how we have the same value repeated for each day in the month it belongs to. This will allow us to calculate the percentage of the monthly precipitation that occurred each day and then pull out the largest values:

```
1 weather\
      .query('datatype == "PRCP"')\
 2

```

transform() can be used on dataframes as well. We can use it to easily standardize the data:

```
1 fb[['open', 'high', 'low', 'close']].transform(
2 lambda x: (x - x.mean()).div(x.std())
3 ).head()

open high low close

2018-01-08 0.80 0.79 0.85 0.84
```

#### Pivot tables and crosstabs

We saw pivots in before; however, we weren't able to provide any aggregations. With pivot\_table(), we get the mean by default as the aggfunc. In its simplest form, we provide a column to place along the columns:

```
1 fb.pivot_table(columns='trading_volume')
```

trading_volume	low	med	high	
close	171.43	175.14	168.16	11.
high	173.46	179.42	170.48	
low	169.31	172.11	161.57	
open	171.36	175.82	167.73	
volume	24547207.71	79072559.12	141924023.33	

By placing the trading volume in the index, we get the aggregation from the first example in the group by section above:

1 fb.pivot\_table(index='trading\_volume')

	close	high	low	open	volume	
trading_volume						ılı
low	171.43	173.46	169.31	171.36	24547207.71	
med	175.14	179.42	172.11	175.82	79072559.12	
high	168.16	170.48	161.57	167.73	141924023.33	

With pivot(), we also weren't able to handle multi-level indices or indices with repeated values. For this reason we haven't been able to put the weather data in the wide format. The pivot\_table() method solves this issue:

```
1 weather.reset_index().pivot_table(
2    index=['date', 'station', 'station_name'],
3    columns='datatype',
4    values='value',
5    aggfunc='median'
6 ).reset_index().tail()
```

datatype	date	station	station_name	AWND	DAPR	MDPR	PGTM	PRC
28740	2018- 12-31	GHCND:USW00054787	FARMINGDALE REPUBLIC AIRPORT, NY US	5.00	NaN	NaN	2052.00	28.7
28741	2018- 12-31	GHCND:USW00094728	NY CITY CENTRAL PARK, NY US	NaN	NaN	NaN	NaN	25.9
28742	2018- 12-31	GHCND:USW00094741	TETERBORO AIRPORT, NJ US	1.70	NaN	NaN	1954.00	29.2
28743	2018- 12-31	GHCND:USW00094745	WESTCHESTER CO AIRPORT, NY US	2.70	NaN	NaN	2212.00	24.4
28744	2018- 12-31	GHCND:USW00094789	JFK INTERNATIONAL AIRPORT, NY US	4.10	NaN	NaN	NaN	31.2

5 rows × 30 columns

We can use the pd.crosstab() function to create a frequency table. For example, if we want to see how many low-, medium-, and high-volume trading days Facebook

2

3

4

```
1 p.crosstab(
      index=fb.trading_volume,
      columns=fb.index.month,
      colnames=['month'] # name the columns index
5)
     trading_volume
           low
                          19
                              15
                                  20
                                       22
                                           21
                                               18
                                                   23
                                                       19
                                                           23
                                                               21
                                                                    19
          med
                           0
                               4
                                    1
                                        0
                                            0
                                                2
                                                    0
                                                        0
          high
                       0
                           0
                               2
                                   0
                                       0
                                            0
                                                1
                                                    0
                                                        0
                                                            0
                                                                0
```

We can normalize with the row or column totals with the normalize parameter. This shows percentage of the total:

```
1 p.crosstab(
     index=fb.trading_volume,
3
     columns=fb.index.month,
     colnames=['month'],
5
     normalize='columns'
6)
              month
                                   3
                                                                         10
                                                                               11
                                                                                    12
     trading_volume
          low
                     0.95 1.00 0.71 0.95 1.00
                                                 1.00 0.86
                                                            1.00
                                                                  1.00
                                                                       1.00
                                                                             1.00
                                                                                   1.00
          med
                          0.00 0.19 0.05
                                           0.00
                                                 0.00
                                                       0.10
                                                            0.00
                                                                  0.00
                                                                       0.00
                                                                             0.00
                                                                                   0.00
          high
                     0.00 0.00 0.10 0.00 0.00 0.00 0.05 0.00
                                                                  0.00
                                                                       0.00
                                                                            0.00
                                                                                  0.00
```

If we want to perform a calculation other than counting the frequency, we can pass the column to run the calculation on to values and the function to use to aggfunc:

```
1 p.crosstab(
     index=fb.trading_volume,
     columns=fb.index.month,
3
     colnames=['month'],
4
5
     values=fb.close,
     aggfunc=ny.mean
6
7 )
             month
                                        3
                                                       5
                                                                      7
                                                                                     9
    trading_volume
                     185.24 180.27 177.07 163.29 182.93 195.27
                                                                 201.92 177.49 164.38
          low
          med
                     179.37
                              NaN 164.76 174.16
                                                     NaN
                                                            NaN
                                                                 194.28
                                                                           NaN
                                                                                  NaN
          hiah
                      NaN
                              NaN 164.11
                                                    NaN
                                                            NaN 176.26
                                                                           NaN
                                                                                  NaN
                                             NaN
```

We can also get row and column subtotals with the margins parameter. Let's count the number of times each station recorded snow per month and include the subtotals:

```
1 snow_data = weather.query('datatype == "SNOW"')
2 p.crosstab(
3
    index=snow_data.station_name,
4
     columns=snow_data.index.month,
5
     colnames=['month'],
     values=snow_data.value,
     aggfunc=lambda x: (x > 0).sum(),
```

- 8 margins=True, # show row and column subtotals
- 9 margins\_name='total observations of snow' # name the subtotals

10)
