Aggregations with pandas and numpy

Name: Cuadra, Audrick Zander G.

Section: CPE22S3

Date: March 27, 2024

Submitted to: Engr. Roman Richard

About the data

In this notebook, we will be working with 2 data sets:

- Facebook's stock price throughout 2018 (obtained using the stock_analysis package).
- daily weather data for NYC from the <u>National Centers for Environmental Information (NCEI)</u>
 <u>API</u>.

Note: The NCEI is part of the National Oceanic and Atmospheric Administration (NOAA) and, as you can see from the URL for the API, this resource was created when the NCEI was called the NCDC. Should the URL for this resource change in the future, you can search for the NCEI weather API to find the updated one.

Background on the weather data

Data meanings:

- AWND: average wind speed
- PRCP: precipitation in millimeters
- SNOW: snowfall in millimeters
- SNWD: snow depth in millimeters
- TMAX: maximum daily temperature in Celsius
- TMIN: minimum daily temperature in Celsius

Setup

```
1 import numpy as ny
2 import pandas as p
3
4 weather = p.read_csv('/content/weather_by_station.csv', index_col='date', parse_dates=
5 weather.head()
```

	datatype	station	value	station_name
date				
2018-01-01	PRCP	GHCND:US1CTFR0039	0.0	STAMFORD 4.2 S, CT US
2018-01-01	PRCP	GHCND:US1NJBG0015	0.0	NORTH ARLINGTON 0.7 WNW, NJ US
2018-01-01	SNOW	GHCND:US1NJBG0015	0.0	NORTH ARLINGTON 0.7 WNW, NJ US
2018-01-01	PRCP	GHCND:US1NJBG0017	0.0	GLEN ROCK 0.7 SSE, NJ US
2018-01-01	SNOW	GHCND:US1NJBG0017	0.0	GLEN ROCK 0.7 SSE, NJ US

```
1 fb = p.read_csv('/content/fb_2018.csv', index_col='date', parse_dates=True).assign(
2     trading_volume=lambda x: p.cut(x.volume, bins=3, labels=['low', 'med', 'high'])
3 )
4 fb.head()
```

	open	high	low	close	volume	trading_volume
date						
2018-01-02	177.68	181.58	177.5500	181.42	18151903	low
2018-01-03	181.88	184.78	181.3300	184.67	16886563	low
2018-01-04	184.90	186.21	184.0996	184.33	13880896	low
2018-01-05	185.59	186.90	184.9300	186.85	13574535	low
2018-01-08	187.20	188.90	186.3300	188.28	17994726	low

Before we dive into any calculations, let's make sure pandas won't put things in scientific notation. We will modify how floats are formatted for displaying. The format we will apply is .2f, which will provide the float with 2 digits after the decimal point:

```
1 p.set_option('display.float_format', lambda x: '%.2f' % x)
```

Summarizing DataFrames

We learned about agg() in the dataframe operations notebook when we learned about window calculations; however, we can call this on the dataframe directly to aggregate its contents into a single series:

```
1 fb.agg({
2
    'open': ny.mean,
3
     'high': ny.max,
    'low': ny.min,
4
5
     'close': ny.mean,
     'volume': ny.sum
6
7 })
                171.45
   open
   high
                 218.62
   low
                 123.02
   close
                 171.51
   volume 6949682394.00
   dtype: float64
```

We can use this to find the total snowfall and precipitation recorded in Central Park in 2018:

```
1 weather.query(
2   'station == "GHCND:USW00094728"'
3 ).pivot(columns='datatype', values='value')[['SNOW', 'PRCP']].sum()

   datatype
   SNOW   1007.00
   PRCP   1665.30
   dtype: float64
```

This is equivalent to passing 'sum' to agg():

```
1 weather.query(
2    'station == "GHCND:USW00094728"'
3 ).pivot(columns='datatype', values='value')[['SNOW', 'PRCP']].agg('sum')

    datatype
    SNOW    1007.00
    PRCP    1665.30
    dtype: float64
```

Note that we aren't limited to providing a single aggregation per column. We can pass a list, and we will get a dataframe back instead of a series. nan values are placed where we don't have a calculation result to display:

```
1 fb.agg({
2    'open': 'mean',
3    'high': ['min', 'max'],
4    'low': ['min', 'max'],
5    'close': 'mean'
6 })
```

	open	high	low	close
mean	171.45	NaN	NaN	171.51
min	NaN	129.74	123.02	NaN
max	NaN	218.62	214.27	NaN

v Using groupby()

Often we won't want to aggregate on the entire dataframe, but on groups within it. For this purpose, we can run <code>groupby()</code> before the aggregation. If we group by the <code>trading_volume</code> column, we will get a row for each of the values it takes on:

1 fb.groupby('trading_volume').mean()

	open	high	low	close	volume
trading_volume					
low	171.36	173.46	169.31	171.43	24547207.71
med	175.82	179.42	172.11	175.14	79072559.12
high	167.73	170.48	161.57	168.16	141924023.33

After we run the <code>groupby()</code>, we can still select columns for aggregation

1 fb.groupby('trading_volume')['close'].agg(['min', 'max', 'mean'])

	min	max	mean
trading_volume			
low	124.06	214.67	171.43
med	152.22	217.50	175.14
high	160.06	176.26	168.16

We can still provide a dictionary specifying the aggregations to perform, but passing a list for a column will result in a hierarchical index for the columns:

```
1 fb_agg = fb.groupby('trading_volume').agg({
2    'open': 'mean',
3    'high': ['min', 'max'],
4    'low': ['min', 'max'],
5    'close': 'mean'
6 })
7 fb_agg
```

	open	high		low		close
	mean	min	max	min	max	mean
trading_volume						
low	171.36	129.74	216.20	123.02	212.60	171.43
med	175.82	162.85	218.62	150.75	214.27	175.14
high	167.73	161.10	180.13	149.02	173.75	168.16

The hierarchical index in the columns looks like this:

Using a list comprehension, we can join the levels (in a tuple) with an _ at each iteration:

```
1 fb_agg.columns = ['_'.join(col_agg) for col_agg in fb_agg.columns]
2 fb agg.head()
```

	open_mean	8	8			
trading_volume						
low	171.36	129.74	216.20	123.02	212.60	171.43
med	175.82	162.85	218.62	150.75	214.27	175.14
high	167.73	161.10	180.13	149.02	173.75	168.16

open mean high min high max low min low max close mean

We can group on datetimes despite them being in the index if we use a Grouper:

```
1 weather['2018-10'].query('datatype == "PRCP"').groupby(
2    p.Grouper(freq='D')
3 ).mean().head()
```

```
<ipython-input-17-927d8e720cd7>:1: FutureWarning: Indexing a DataFrame with a datetim
  weather['2018-10'].query('datatype == "PRCP"').groupby(
<ipython-input-17-927d8e720cd7>:3: FutureWarning: The default value of numeric_only i
  ).mean().head()
```

value

WAYNE TWP 0.8 SSW, NJ US

date	
2018-10-01	0.01
2018-10-02	2.23
2018-10-03	19.69
2018-10-04	0.32
2018-10-05	0.97

This Grouper can be one of many group by values. Here, we find the quarterly total precipitation per station:

```
1 weather.query('datatype == "PRCP"').groupby(
     ['station_name', p.Grouper(freq='Q')]
3 ).sum().unstack().sample(5, random_state=1)
    <ipython-input-20-648f26f48c8d>:3: FutureWarning: The default value of numeric only i
      ).sum().unstack().sample(5, random_state=1)

                                                               438.80
                                                                           409.90
       SYOSSET 2.0 SSW, NY US
                                      323.50
                                                   263.30
                                                               355.50
                                                                           459.90
       STAMFORD 4.2 S, CT US
                                       338.00
                                                   272.10
                                                               424.70
                                                                           390.00
```

Note that we can use filter() to exclude some groups from aggregation. Here, we only keep groups with 'NY' in the group's name attribute, which is the station ID in this case:

246.20

295.30

620.90

422.00

```

```

Let's see which months have the most precipitation. First, we need to group by day and average the precipitation across the stations. Then we can group by month and sum the resulting precipitation. We use <code>nlargest()</code> to give the 5 months with the most precipitation:

Perhaps the previous result was surprising. The saying goes "April showers bring May flowers"; yet April wasn't in the top 5 (neither was May for that matter). Snow will count towards precipitation, but that doesn't explain why summer months are higher than April. Let's look for days that accounted for a large percentage of the precipitation in a given month.

In order to do so, we need to calculate the average daily precipitation across stations and then find the total per month. This will be the denominator. However, in order to divide the daily values by the total for their month, we will need a Series of equal dimensions. This means we will need to use transform():

```
1 weather.query('datatype == "PRCP"').rename(
     dict(value='prcp'), axis=1
3 ).groupby(p.Grouper(freq='D')).mean().groupby(
     p.Grouper(freq='M')
5 ).transform(ny.sum)['2018-01-28':'2018-02-03']
    <ipython-input-24-1e336928755e>:3: FutureWarning: The default value of numeric only i
      ).groupby(p.Grouper(freq='D')).mean().groupby(
                 prcp
          date
    2018-01-28 69.31
    2018-01-29 69.31
    2018-01-30 69.31
    2018-01-31 69.31
    2018-02-01 158.11
    2018-02-02 158.11
    2018-02-03 158.11
```

Notice how we have the same value repeated for each day in the month it belongs to. This will allow us to calculate the percentage of the monthly precipitation that occurred each day and then pull out the largest values:

```
1 weather\
       .query('datatype == "PRCP"')\
2
      .rename(dict(value='prcp'), axis=1)\
3
4
      .groupby(p.Grouper(freq='D')).mean()\
5
      .assign(
      total_prcp_in_month=lambda x: x.groupby(
6
7
           p.Grouper(freq='M')
8
      ).transform(ny.sum),
      pct_monthly_prcp=lambda x: x.prcp.div(
9
           x.total_prcp_in_month
10
11
      ).nlargest(5, 'pct monthly prcp')
12
```

<ipython-input-26-ec955deab43a>:4: FutureWarning: The default value of numeric_only i
 .groupby(p.Grouper(freq='D')).mean()\

prcp total prcp in month pct monthly prcp

transform() can be used on dataframes as well. We can use it to easily standardize the data:

```
1 fb[['open', 'high', 'low', 'close']].transform(
2    lambda x: (x - x.mean()).div(x.std())
3 ).head()
```

	open	high	low	close
date

2018-01-04	0.68	0.65	0.74	0.64
2018-01-05	0.72	0.68	0.78	0.77
2018-01-08	0.80	0.79	0.85	0.84

Pivot tables and crosstabs

We saw pivots in before; however, we weren't able to provide any aggregations. With pivot_table(), we get the mean by default as the aggfunc. In its simplest form, we provide a column to place along the columns:

```
1 fb.pivot_table(columns='trading_volume')
```

trading_volume	low	med	high
close	171.43	175.14	168.16
high	173.46	179.42	170.48
low	169.31	172.11	161.57
open	171.36	175.82	167.73
volume	24547207.71	79072559.12	141924023.33

By placing the trading volume in the index, we get the aggregation from the first example in the group by section above:

1 fb.pivot_table(index='trading_volume')

	close	high	low	open	volume
trading_volume					
low	171.43	173.46	169.31	171.36	24547207.71
med	175.14	179.42	172.11	175.82	79072559.12
high	168.16	170.48	161.57	167.73	141924023.33

With pivot(), we also weren't able to handle multi-level indices or indices with repeated values. For this reason we haven't been able to put the weather data in the wide format. The pivot_table() method solves this issue:

```
1 weather.reset_index().pivot_table(
2    index=['date', 'station', 'station_name'],
3    columns='datatype',
4    values='value',
5    aggfunc='median'
6 ).reset_index().tail()
```

datatype	date	station	station_name	AWND	DAPR	MDPR	PGTM	PRCF
28740	2018- 12-31	GHCND:USW00054787	FARMINGDALE REPUBLIC AIRPORT, NY US	5.00	NaN	NaN	2052.00	28.70

5 rows × 30 columns

1 p.crosstab(

We can use the pd.crosstab() function to create a frequency table. For example, if we want to see how many low-, medium-, and high-volume trading days Facebook

```
index=fb.trading_volume,
     columns=fb.index.month,
4
     colnames=['month'] # name the columns index
5)
             month
                                                 9 10 11 12
    trading_volume
                   20 19 15 20 22 21 18 23 19 23 21 19
         low
         med
                           4
                              1
                                  0
                                     0
                                          2
                                                 0
                                                     0
                        0
         high
                    0
                        0
                           2
                               0
                                  0
                                     0
                                          1
                                             0
                                                 0
                                                     0
```

We can normalize with the row or column totals with the normalize parameter. This shows percentage of the total:

2

3

4

5

1 p.crosstab(

```
index=fb.trading_volume,
      columns=fb.index.month,
      colnames=['month'],
      normalize='columns'
6)
                month
                                       3
                                                                                  10
                                                                                        11
                                                                                               12
     trading_volume
                        0.95 1.00 0.71 0.95 1.00 1.00 0.86 1.00 1.00
            low
                                                                               1.00
                                                                                     1.00 1.00
           med
                        0.05 0.00 0.19 0.05 0.00 0.00
                                                             0.10 0.00 0.00 0.00
                                                                                     0.00
                                                                                            0.00
           high
                        0.00 \quad 0.00 \quad 0.10 \quad 0.00 \quad 0.00 \quad 0.05 \quad 0.00 \quad 0.00 \quad 0.00 \quad 0.00 \quad 0.00
```

If we want to perform a calculation other than counting the frequency, we can pass the column to run the calculation on to values and the function to use to aggfunc:

```
1 p.crosstab(
      index=fb.trading_volume,
3
      columns=fb.index.month,
      colnames=['month'],
4
5
      values=fb.close,
6
      aggfunc=ny.mean
7)
              month
                          1
                                 2
                                         3
                                                        5
                                                                                      9
    trading volume
                     185.24
                            180.27 177.07 163.29
                                                  182.93 195.27
                                                                  201.92
                                                                         177.49 164.38
          low
                                                                                         15
                                                     NaN
          med
                     179.37
                                   164.76
                                           174.16
                                                                  194.28
                                                                                    NaN
                              NaN
                                                             NaN
                                                                            NaN
                                                             NaN 176.26
          high
                       NaN
                              NaN 164.11
                                             NaN
                                                     NaN
                                                                            NaN
                                                                                    NaN
```

We can also get row and column subtotals with the margins parameter. Let's count the number of times each station recorded snow per month and include the subtotals:

```
1 snow data = weather.query('datatype == "SNOW"')
2 p.crosstab(
3
      index=snow_data.station_name,
4
      columns=snow data.index.month,
      colnames=['month'],
5
      values=snow_data.value,
6
7
      aggfunc=lambda x: (x > 0).sum(),
8
      margins=True, # show row and column subtotals
9
      margins_name='total observations of snow' # name the subtotals
10)
```

Comments and Insights

The module topic demonstrates Aggregations. The module displays proper techniques in summarizing and grouping data with the use of different functions and module attribute which makes data presentation look more neat and organize.
